

Call Analysis - features (scope for funding: R0, R1, R1.5)

Each feature is complete when its completion signal is true.

Release	ID	Feature	Description	Completion signal
R0 Groundwork	F1	Analytics data model	One analysis record per call and one topic record per distinct subject discussed (one-to-many). Each topic holds its category, subcategory, the category-list version and a short description of what was discussed, kept for later discovery. The structure allows detail to be added per topic later without breaking changes. Group, caller type and channel are taken from the existing interaction data, not copied.	Tables are reviewed with reporting engineering; a sample call with two topics is stored and read back correctly.
	F2	Category list storage with versions and audit trail	Tables for the category and subcategory tree, client-specific lists, versions and where each list applies (payer, plan, group, subgroup). A change creates a new version; earlier versions are kept. Every change records who made it and when. No editing screen yet.	A change creates a new version, the previous version is unchanged, and the change shows who made it and when.
	F3	Category list v1 agreed with the call center	First member and provider category and subcategory lists, drafted by the team and reviewed with the call center leads. Loaded as version 1.	Call center leads have signed off the member and provider lists, and version 1 is loaded.
	F4	Client-specific lists and opt-out	CareSource Ohio PCIR and PCDR categories loaded and tied to the payer; plans that do not approve AI processing are listed for exclusion.	CareSource categories apply only to CareSource calls, and calls from excluded plans are not processed.
R1 Every call categorized	F5	Call analysis service triggered from Genesys	A separate service that Genesys calls when a transcript is ready, for the queues configured for categorization. Independent of call summarization, so IVR-only calls can be included. Starts with Genesys; other sources can be added later. Approach to be confirmed with the business.	Calls on a configured queue reach the service automatically; calls on other queues do not.
	F6	Topic breakdown and categorization	Each transcript is split into the distinct topics discussed (for example crown coverage, then finding a dentist; or the same question about three patients). Each topic gets a category and subcategory from the active list, plus any client-specific list that applies, and a short summary of what was discussed (since a call summary is not guaranteed when this runs separately from call summarization). Category and subcategory only.	Every call on the configured queues is split into topics, and each topic has a category and subcategory, with no manual step.
	F7	Primary category per call	Each call also records its primary category, so reports can count calls as well as topics.	Every categorized call has exactly one primary category.
	F8	Data in Snowflake for analytics tools	The new tables flow to Snowflake through the existing stream, where they can be combined with group, member and plan data in Power BI, Tableau or other Snowflake analytics tools.	An analyst can query the categorized data in Snowflake with current data and join it to group data.
	F9	Category report	Number and share of calls and topics by category and subcategory, selectable by group, payer or caller type, for any period.	The report can be produced for any group or payer and a chosen period.
	F10	CareSource PCIR and PCDR data	Calls are categorized against the CareSource Ohio lists so that the monthly PCIR and PCDR reports can be produced from this data. Producing the reports themselves is a separate effort.	One month of CareSource calls is categorized against the PCIR and PCDR lists and the counts are available.
R1.5 Category discovery	F11	Category discovery	Clustering over the stored topic descriptions from historical calls, to find groups of topics that do not fit the current list well, including what lands in 'other'.	A discovery run over historical calls produces candidate categories, each with call volume and example topics.
	F12	Review and adoption of discovered categories	Candidates are reviewed with the call center. Approved additions are published as a new version of the list (by the team, no editing screen yet) and used for new calls.	Reviewed candidates are recorded as approved or rejected, and approved ones are in use for new calls.

Call Analysis - future features (direction only, not estimated)

Shown for context. These would be re-scoped after R1.5.

Release	ID	Feature	Description	Completion signal
R2 Drill-down detail and dashboard	F13	AI-assisted drill-down design	For a chosen subcategory, AI reviews a sample of its calls and suggests what details are worth capturing; the business confirms.	Suggested details for at least one subcategory are reviewed and confirmed.
	F14	Drill-down capture per subcategory	A per-subcategory step captures the confirmed details on new calls and stores them without schema changes.	Confirmed details are captured automatically for the chosen subcategories.
	F15	Targeted reprocessing	When a subcategory's details change, re-run only the calls in that subcategory or date range.	Changing one subcategory reprocesses only its calls.
	F16	Interactive dashboard	Dashboard on Snowflake: top categories by volume for 30, 60 or 90 days, filters by caller type, group and program, drill into captured details.	A user drills from category to subcategory to captured detail.
R3 Trends, chatbot and business-managed categories	F17	Trend analysis	Period-over-period comparison, overall or within one group.	The dashboard shows change between two periods.
	F18	Chatbot sessions	Chatbot conversations categorized, with whether the request was fulfilled.	Chatbot sessions appear in the analysis with an outcome.
	F19	Business-managed categories	A screen for the business to review proposals, approve changes and manage versions.	A business user publishes a change without a feature-team request.
R4 Ask questions of the data	F20	Chat with the data	Plain-language questions answered from the data. Uses existing tools (Snowflake semantic layer, Power BI, Tableau or a Cowork type assistant) where they can do the job; built only if they cannot.	A plain-language question returns a correct answer.
	F21	Keyword and ad-hoc search	Keyword search and filters over calls and topics for a date range.	A keyword search returns matching calls and topics.
	F22	Routing and misroute analysis	Original queue vs the caller's actual group; calls meant for other Delta Dental plans. Needs Genesys queue data.	A report shows wrong-queue and other-plan counts.
